- Relative role of prosody and statistical computation in the segmentation of continuous speech
- Role of prosody and distributional regularities in the acquisition of word order
- Why linguistic change goes in one direction?
- For each of these 3 areas I will make a brief summary of the progress we made.

- Phonemic distinctions, in particular consonantal distinctions (Nespor, Peña and Mehler 2002; Bonatti, Peña, Nespor and Mehler 2005; Nazzi 2005), give primarily cues to the lexicon, and much less to grammar.
- Humans can segment continuous speechstreams exclusively on the basis of TP calculation between syllables.
- If TPs are kept high between Cs but not between syllables (the syllables contain many different vowels) the ability to detect words is still very high.
- If the TPs are high between Vs (the syllables contain many different consonants) the ability to parse the stream is destroyed.
(Peña 2002; Bonatti, Peña, Nespor and Mehler 2005)

- TPs vs prosody in speech segmentation
(Shukla, Nespors and Mehler 2007)

- We added prosodic characteristics to frames of 10 syllables such that the prosodic constituents would be aligned with the frames.
- The prosodic characteristics were those of different Italian Intonational Phrases (Nespor & Vogel 1986).
- In each pitch contour: an initial syllable is 200msec long, followed by eight syllables of 240msec each, and a final, lengthened syllable of 280msec.
- In the test phase, the subjects were presented orally with pairs of words and part-words with a *flat prosody* (a constant pitch of 100Hz and all phonemes with the same length of 120msec).

Adding Prosody

- Each FRAME is given the acoustic pattern of one of a series of recorded Italian IPs
- Pitch + Length characteristics of IPs

- Given that we are interested in language acquisition in the first months of life, we must show that the effect of prosody is due to universal properties.
- It could in fact be the case that Italian adults might have learned to associate the edges of IPs to the edges of words.
- We thus need evidence that prosody never heard before can aid in segmenting fluent speech. We decided to superimpose Japanese contours to the same stream used in the first experiment.

- Thus some aspects of the prosody of IPs, common also to phrases in music, appear to offer a universal signal to subsequences of streams of fluent speech (e.g. pitch decline at the right edge).
- We have also shown that TPs are in fact calculated automatically in all positions and that prosody has the effect of filtering out those words that are prosodically ill-formed.

Role of prosody and distributional regularities in the acquisition of word order

- We hypothesized that the iambic - trochaic law determines the physical realization of prominence at the level of the phonological phrase: if both pitch and intensity are strongest on the same syllable, then grouping is trochaic; else it is iambic. (Nespor, Shukla, Avesani, van de Vijver, Schraudolf and Donati, submitted).

- We have shown this to be the case both interlinguistically (French and Turkish) and intralinguistically (German).
- Since the iambic trochaic law is a mechanism of perception also for music (Bolton 1894, Woodrow 1951, Cooper and Meyer 1960), we conclude that a general mechanism of perception can give a cue to the relative order of heads and complements.

Distributional cues to word order

- Prosody is not the only cue to word order:
- Frequency provides reliable cues to functional categories
- The relative order of frequent and infrequent words provides reliable cues to word order
- Are infants able to pick up these cues?
- Even in the prelexical stage?

- We tested prelexical infants (7 months old) with the headturn preference paradigm.
- Italian and Japanese infants show opposite preference for initial or final functor
- Thus one more proof that the acquisition of structure proceeds independently of the knowledge of the lexicon

Results

Why does (attested) changes in word order go in only one direction?

- If languages undergo change in word order, this goes from OV to VO.
- Thus there must be an advantage for VO.
- The question is then why so many languages are OV, even the ancestors of many VO.
- Hypothesis: VO is preferred for grammatically governed language; OV is the preferred order for communication.

Evidence for SOV in Communication in the gestural modality

- Home-signs

(Goldin-Meadow & Feldman, 1977; Goldin-Meadow et al, 1994)

- Nicaraguan Sign Language

(Kegl, In Press; Senghas, 2003; Senghas et al., 2004)

- Al-Sayyid Bedouin Sign Language

(Sandler et al., 2005; Padden et al., In Press)

Evidence for SVO in grammatically governed languages

- Creole languages are universally SVO (Bickerton, 1984; 1990)
- Both Ijo (SOV) and Zeelandic Dutch (SOV) → Berbice Dutch (SVO)
- without morphology, SVO resolves the ‘Who-Did-What-To-Whom’ ambiguity most effectively, in case of pro-drop.
